

MDA

$$\tau u^M \quad \tau e^{(u u)M}$$

TE

- consider different cities/geographies, and sensitivities to earthquakes
- i.e. infrastructure to sustain earthquakes

inflow / duration
 $w = f(M)$

- pick cost up front
- u as fixed parameter

$$w = f(M, \text{cost})$$

Linear Programming

Optimization,
constraints

$$\max_x \boxed{\phi(x)} \quad A\vec{x} \leq \vec{b}$$

- minimized missed?
- how to evaluate models?
 - missed
 - alarm
 - how to weight
- user has section on evaluating, best way to quantify how good model was

convex programming
→ open same

- setting up the problem
- prove that the function is convex

- need mathematical function
- Solver will know how to walk through the space

$$w = f(M)$$

w = window, duration

- then what kind of function

* Luen's paper on evaluating Predictors *

$$\max_x \text{ of } \phi(\vec{x}) \quad A\vec{x} \leq \vec{b}$$

← mathematical
function

↳ must be linear?

Linear
Programming

↳ different parameters
convex functions

- find packages online

• prove function is convex (obv. true if linear)

- area under miss v. cost curve

- work on getting integral estimate

- take in either model

vector so can put in ^{many} parameters
